What is a photometric redshift?

Photometric redshift estimation is a **mapping** from the photometric space $\{F_i\}$ to redshift.

What is a photometric redshift?

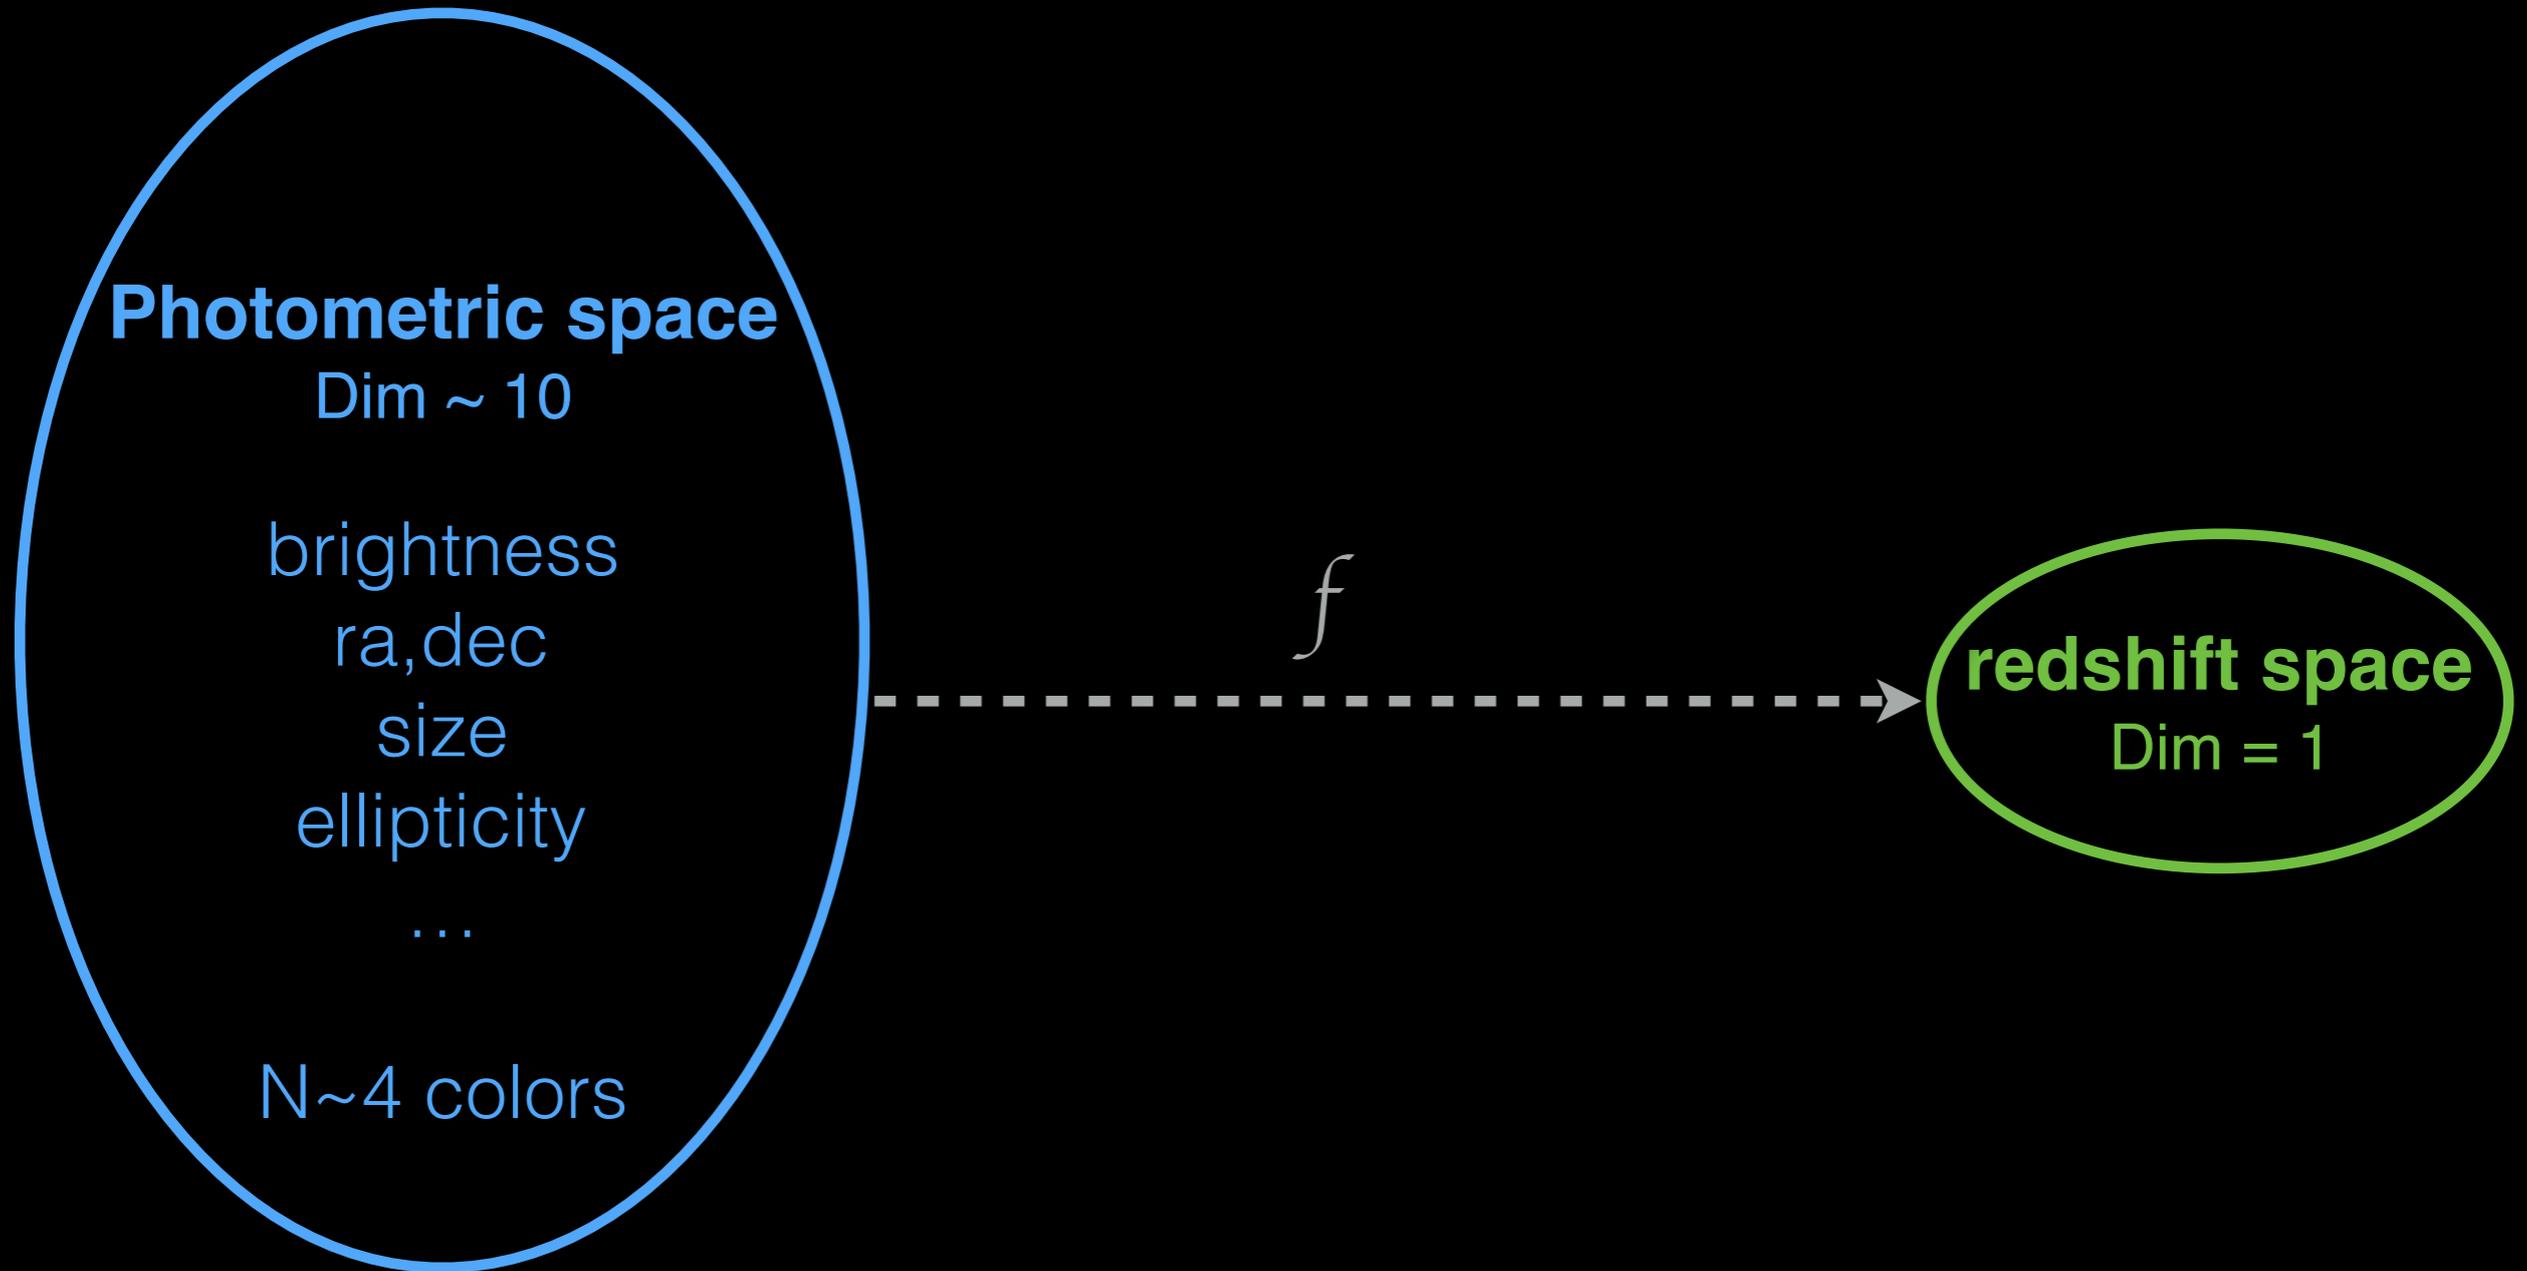

Photometric redshift estimation is a **mapping** from the photometric space $\{F_i\}$ to redshift.

Any measured property in $\{F_i\}$ has an associated noise estimate. A photometric source is not just a point in $\{F_i\}$ but a region defined by the noise level.

$p(z | \{F_i\})$ does not apply to a given object but to a class of objects statistically indistinguishable.

Color-based photometric redshifts are the same for all galaxies with similar colors (set by photometric errors).

Clustering redshifts

We have a new tool in hand to characterize the mapping between the photometric space and redshift

We can already deproject various photometric datasets and obtain meaningful color-redshift tracks.
